TITLE: Electromagnetic stirring in melting stainless steel in electric furnaces

PERIODICAL: Metallurg, no. 4, 1963, 22 - 24

TEXT: Experimental tests have been carried out from 1956 - 1960 with two stators for electromagnetic stirring in steelmelting. The use of these stators proved efficient by intensifying the melting process and improving the quality of the metal. Desulfurization and deoxidation processes were accelerated, slag removal time was reduced by 5 - 7 min, and the chemical composition of the metal produced, approached the theoretical values. The Cr content in the finished steel was corrected to amounts not over 17.5%; this secures considerable savings in ferro-chromium and nickel. As a result the refining time is reduced by 30 - 40 min, and metal rejects decrease by a factor of 2 - 3. The stator can be switched into two positions, namely, "stirring of the pool" and "removal of slag". It was found that the stator operated less efficient in the former position.

A006/A101

The highest speed of metal motion on the pool surface (0.3 - 0.5 m/sec) was observed at a frequency as high as 0.5 - 0.55 cycles and 1,900 - 2,000 amps current strength. There are 2 figures.

The author describes a case of spontaneous rupture of the liver during delivery which was caused by necrosis of the liver and by haemorrhage into the hepatic parenchyma after influenza. Death ensued from bleeding into the abdominal cavity. In the second case described death was caused by spontaneous rupture of the aorta in the bulb in the course of toxæmia.
